

Meiosis

11-4

Chromosome Number

- You have 46 chromosomes in each body cell
- These are grouped into 23 homologous (matching) pairs.
- 23 from mom, 23 from dad
- Diploid = cell that has both (2) sets of chromosomes.
 - Humans: $2N = 46$
 - Fruit fly: $2N = 8$

Gametes

- A new organism (zygote) is formed when two gametes (sperm and ovum) combine
- If gametes each had 46 chromosomes, the offspring would have 92 chromosomes!
- Gametes have $\frac{1}{2}$ the number of chromosomes = haploid
- 1 chromosome from each pair
- Humans: $N = 23$
- Fruit flies: $N = 4$

Meiosis

- Process where homologous chromosomes are separated as diploid cells are divided to produce haploid gametes
- Occurs in reproductive organs (ovaries and testies)
- 2 stages:
 - Meiosis I (separates chromosomes)
 - Meiosis II (separates chromatids)
- End result = 4 haploid gametes (egg or sperm)

Interphase I

- DNA is replicated

Prophase I

- Nuclear envelope breaks down
- Chromosomes are formed (2 chromatids)
- Homologous chromosomes pair up (tetrad)
- Spindle forms

Crossing Over

- Occurs when tetrads form during Meiosis I
- Chromosomes exchange portions of their chromatids
- Results in different allele combos

Metaphase I

- Spindle fibers attach to chromosomes
- Tetrads form in center of cell

Anaphase I

- Homologous chromosomes separate

Telophase I and Cytokinesis

- Nuclear membrane reforms
- Cell divides into 2 haploid cells

Prophase II

- Spindle forms
- Nuclear membrane breaks down

Metaphase II

- Spindle fibers attach to centromeres
- Chromosomes line up in middle

Anaphase II

- Sister chromatids separate

Telophase II and Cytokinesis

- Nuclear envelope reforms
- Cells divide
- End result = 4 haploid gametes
